Leading and
Learning in WASH

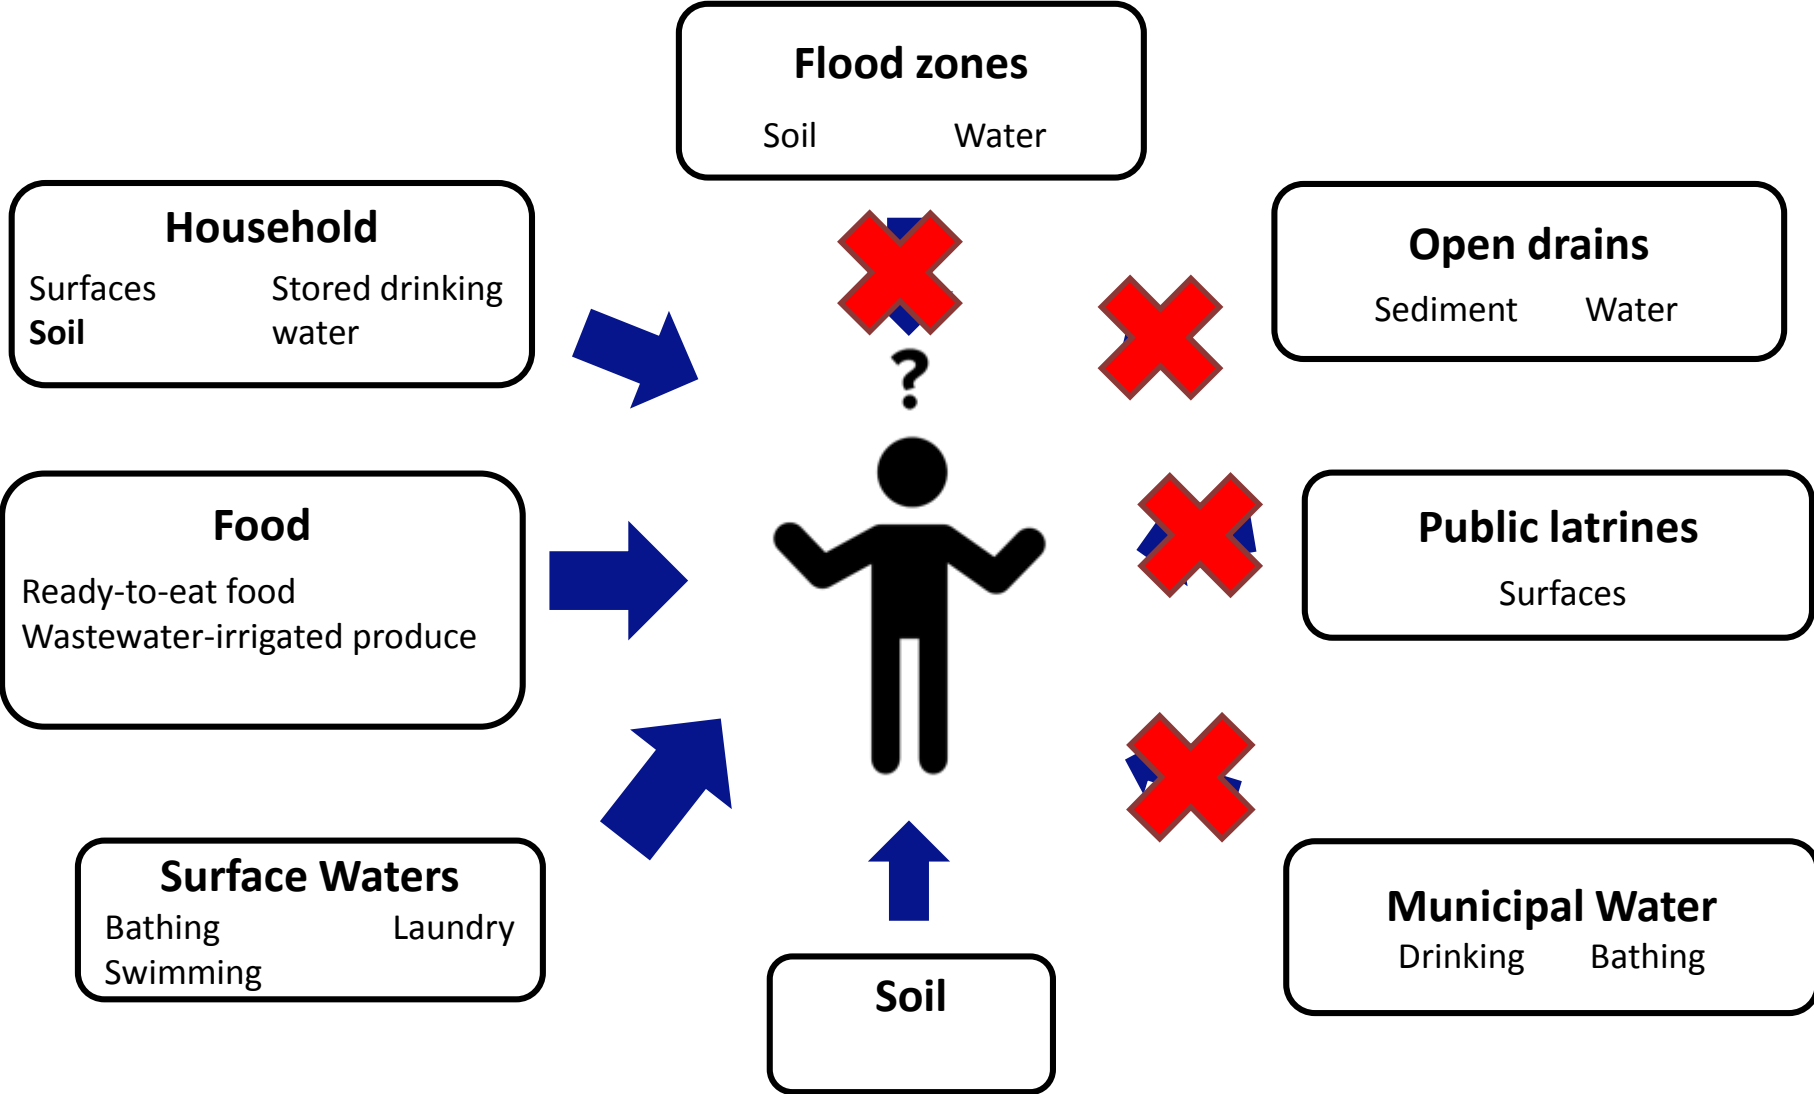

Given complex exposure routes with **different levels of contamination** and **types of exposure contact**, it has been difficult to determine **what kind of interventions might have the biggest impact on reduction in exposure**.

Which pathways pose the greatest risk of exposure?

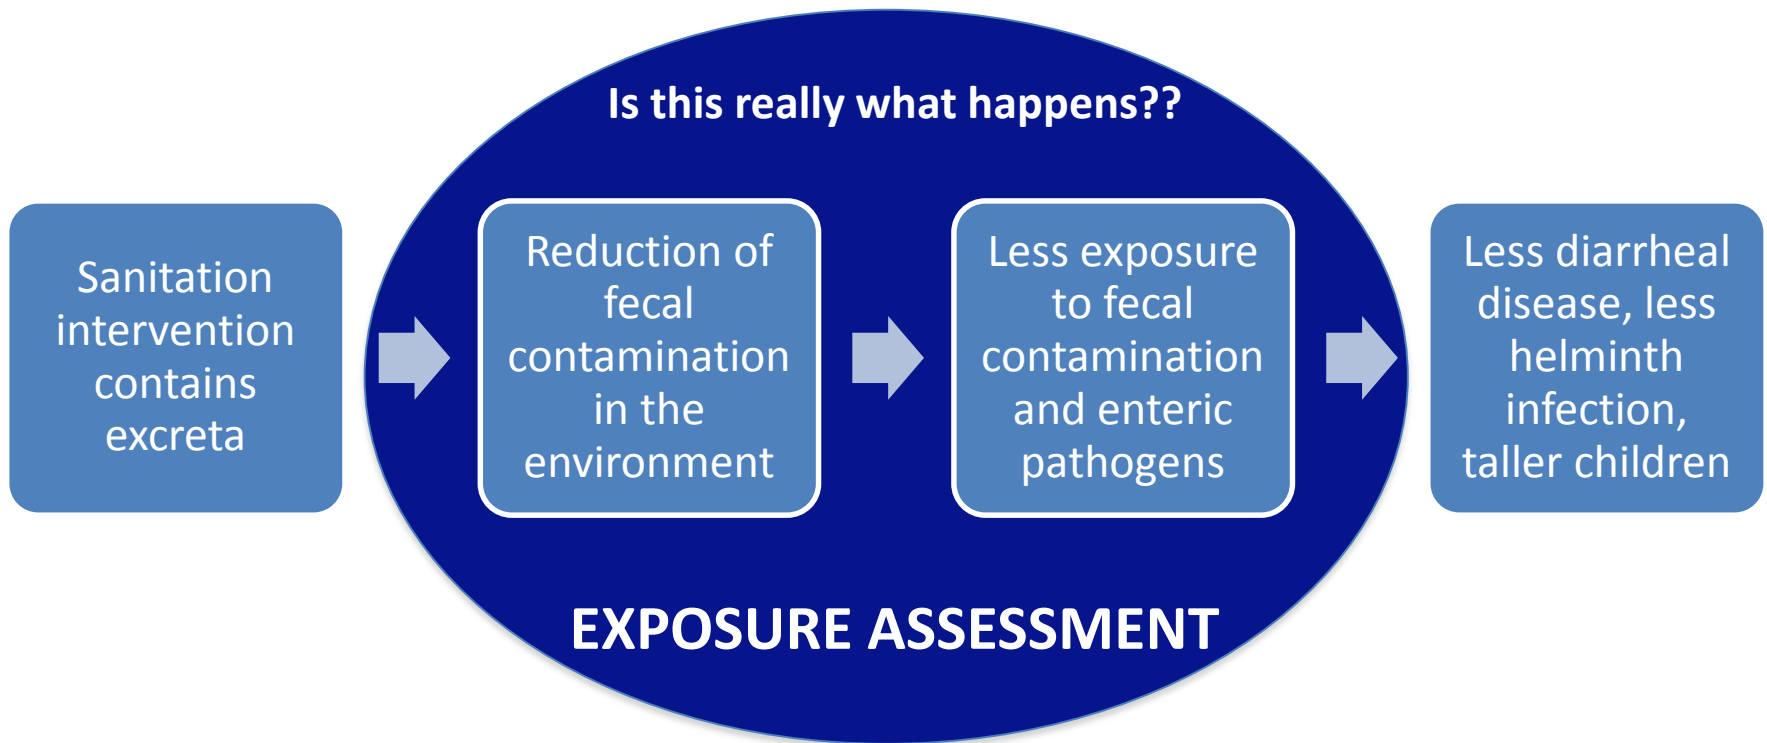

What is driving the risk? (behavior or contamination)

The Tool

The SaniPath Tool is designed to **assess public health risks** related to poor sanitation and to help **prioritize sanitation investments** based on the **exposures** that have the greatest public health impact.

Expected Impact of Sanitation Interventions

Study Objective

Will improved shared latrines reduce exposure to fecal contamination in the environment within low-income urban neighborhoods?

Pathways of Exposure to Fecal Contamination in Maputo

Floodwater

Shared latrines

Open drains

Surface water

Drinking water

Bathing water

Wastewater irrigated produce

Soil

Data Collection Methods

- **Behavioral Exposure Data**
 - reported frequency of behavior of adults and children that leads to exposure to fecal contamination
- **Environmental Microbiology Data**
 - Collect environmental samples from relevant exposure pathways
 - Analyze for *E. coli*

Collecting drain water samples

Adapting Methods for MapSan

- Data collected over 6 weeks (March-April 2015) near end of rainy season
- 15 intervention compounds, 10 control compounds
 - mean 26 people per compound
- Environmental Samples per compound
 - Private Domain
 - 2 latrine swabs (if two latrines)
 - 2 soil samples (1 and 3m from latrine)
 - 1 drain water
 - 1 flood water
 - 1 bathing water
 - Public Domain
 - 2 soil (1 and 3m from entrance)
 - 1 drain
 - 1 flood
- Behavioral Surveys per compound
 - 3 adult
 - 2 child

Estimating Exposure to Fecal Contamination

Behavior Frequency

Frequency of Municipal Drinking Water Contact in Shaibu (adults)

Other parameters:
intake volumes,
duration of
exposure, etc.

Environmental Contamination

Drinking Water (Adult)
Percent Exposed = 89%
Log10 Dose 3.1

Tool uses Bayesian analysis to estimate the distribution of environmental contamination and frequency of exposure.

The mean dose and proportion of the population exposed are summarized from simulated distributions and displayed in risk profiles (left).

SaniPath Risk Profiles Example

Neighborhood in Accra, Ghana

Drinking Water (Adult)

Percent Exposed = 89%

Log10 Dose 3.1

Neighborhood in Vellore, India

Drinking Water (Adult)

Percent Exposed = 97%

Log10 Dose 4.95

Risk profiles show % of population exposed per month (in red) and the average dose of fecal contamination ingested per month (darker red = higher dose).

Pre-Intervention Behaviors

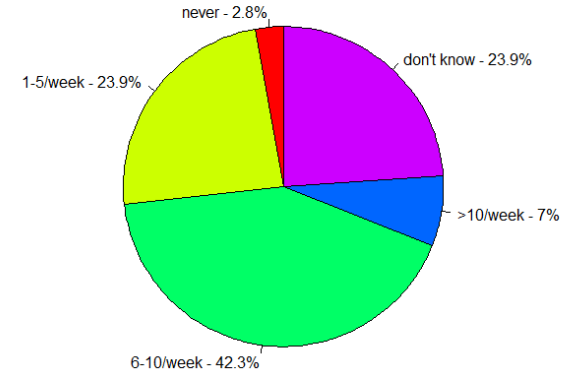

Adult Drain Water Contact

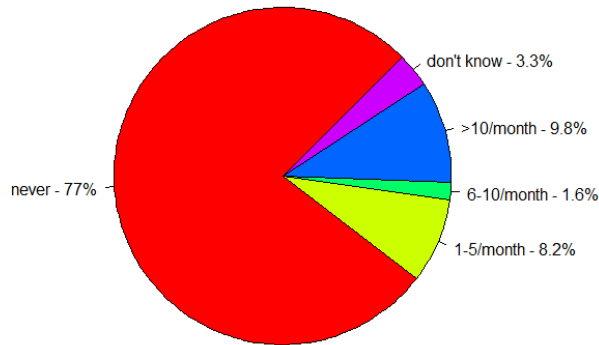

Adult Flood Water Contact

Adult Shared Latrine Contact

Child Drain Water Contact

Child Flood Water Contact

Child Shared Latrine Contact

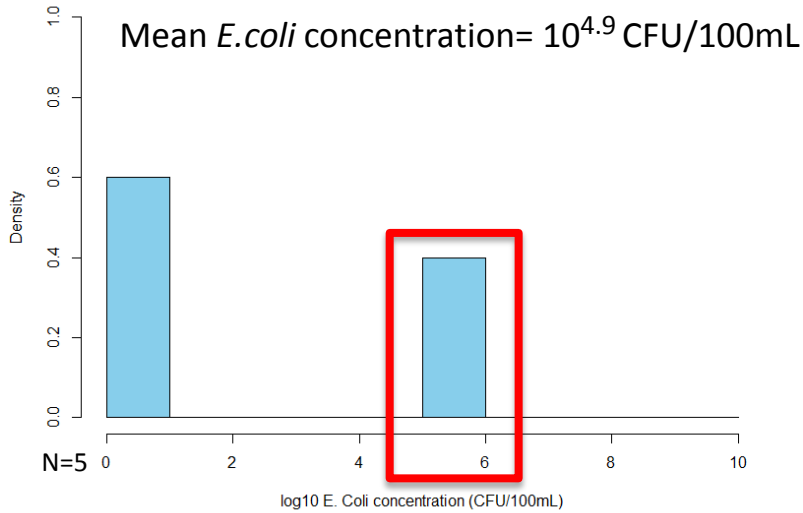

LOW CONTACT

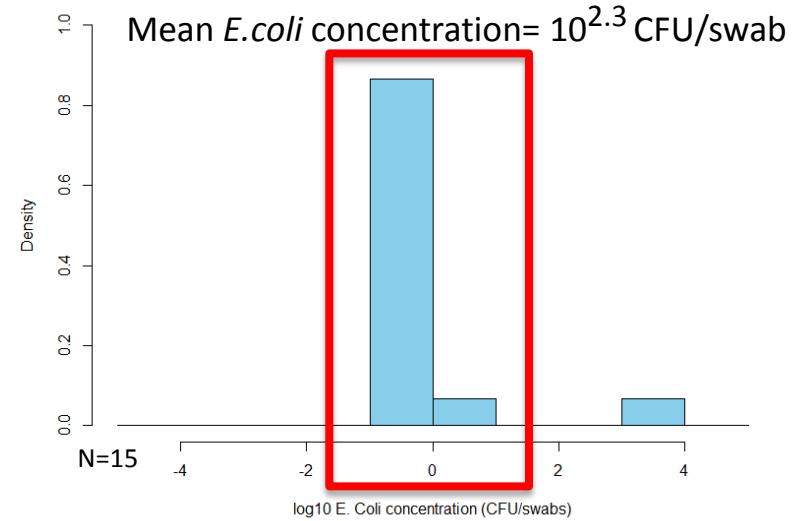

HIGH CONTACT

Pre-Intervention Environmental Contamination

Flood Water

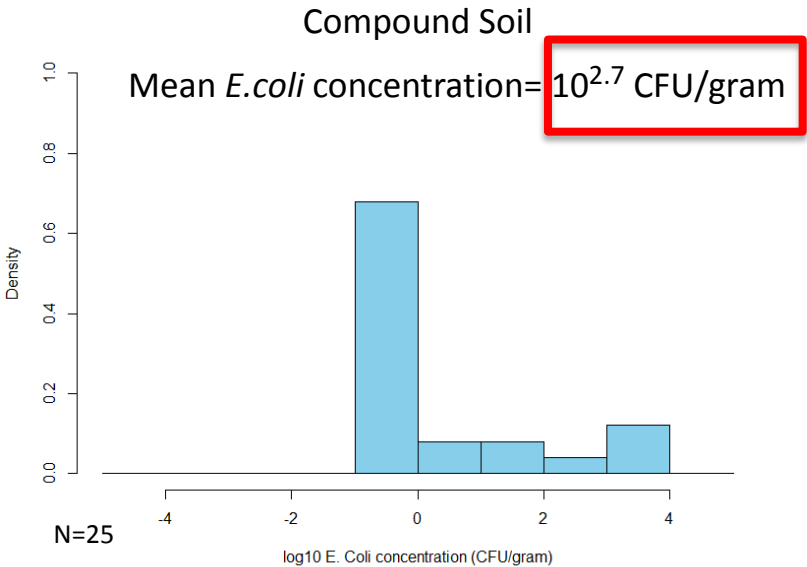

Latrine Swabs

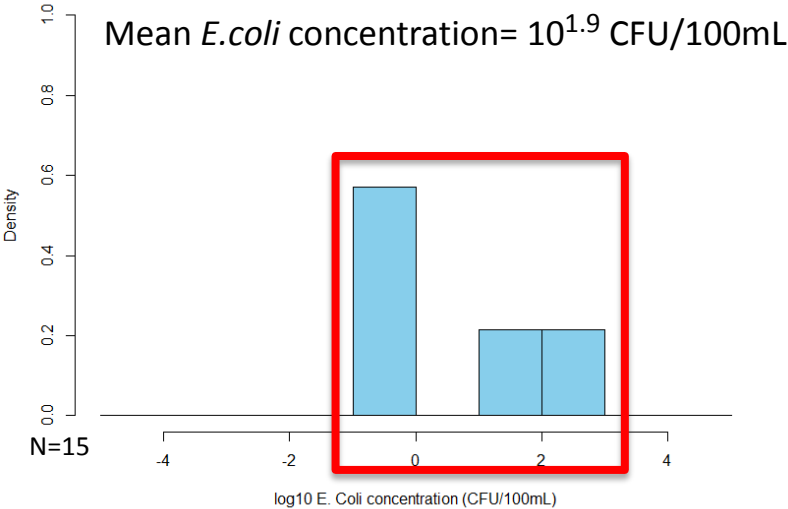

Drain Water

Pre-Intervention Environmental Contamination

Bathing Water

Pre-Intervention Adult Exposure Assessment

Flood Water (Adult)
Percent Exposed=98%
Log10Dose=10.2

Drain Water (Adult)
Percent Exposed=38%
Log10Dose=3.97

Shared Latrines (Adult)
Percent Exposed=100%
Log10Dose=12.4

Pre-Intervention Child Exposure Assessment

Flood Water (Child)
Percent Exposed= 96%
Log10Dose=12.1

Drain Water (Child)
Percent Exposed=23%
Log10Dose=4.58

Shared Latrines (Child)
Percent Exposed=100%
Log10 Dose=11.8

Summary & Next Steps

- Variations in exposure to pathways-
(high/high; low/high)
- Post-intervention data collection in Maputo
March 2016
- Comparison/analysis of pre-intervention and
post-intervention data collection summer
2016
